(57) **ABSTRACT**

A hybrid antenna structure allows the antenna to be used internally or mostly internally in a portable radio communication device operating in the VHF range. The hybrid antenna structure includes a switching circuit that connects an RF circuit to one of several points along the length of a wrapped conductor element, depending on the selected operating frequency. An inductive matching tail element is adjustably tuned to match the selected tap point on the wrapped conductor for the selected operating frequency.

quency. An inductive matching tail is tuned to match the selected tap point on the transformer for the selected operating frequency.

20 Claims, 5 Drawing Sheets

FIG. 1 is a schematic diagram of a matchbox 100. The matchbox 100 is shown in a perspective view, with a top surface and a side surface. A match 130 is positioned on the top surface. The match 130 has a rectangular head with the word "MATCH" printed on it. The matchbox 100 is labeled with the number 100.

HYBRID ANTENNA FOR PORTABLE RADIO COMMUNICATION DEVICES

FIELD OF THE DISCLOSURE

The present disclosure relates generally to antennas for radio devices, and more particularly to hybrid antennas that combine different types of antenna elements together in an antenna structure in order to reduce the overall size of the antenna structure.

BACKGROUND

Portable radio communication devices are widely used to facilitate communication among individuals and within organizations. Cellular phones, for example, are nearly ubiquitous in metropolitan regions around the world. These devices have become so popular that their design is influencing design approaches for other types of portable radio communication devices. One aspect of current cellular phone design that has become standard is the lack of an external antenna. Internal or hidden antennas are instead used for the various transceivers and receivers included in a typical “smart” phone device, and this is a feature that consumers have come to associate with a modern communication device.

Portable two-way radio devices, another type of portable radio communication device, are used to facilitate two-way (i.e. half duplex) radio communication with near instant communication access. These devices typically have a “push to talk” operation which allows a user to commence talking, and to be heard by others, at the push of a button. When a two-way radio device receives a signal on a monitored channel it can simply play received audio/voice signals over a loudspeaker, or a headset/earpiece at virtually the same time as it is being transmitted by the speaker’s two-way radio device. Since two-way radio communication avoids delays present in cellular communication, it has persisted as a communication modality preferred by organizations such as police, fire/rescue, military, and other organizations where near-instant communication is essential.

The adoption of internal antennas in cellular phones, however, has been, in part, facilitated by the evolution of cellular protocols to higher frequencies. Conversely, standardized two-way radio communication is still conducted in Very High Frequency (VHF) bands, which is a much lower frequency than is used in cellular telephony communication. Since antenna size is inversely related to frequency, it has not been practical to adopt antenna designs used in cellular communication into two-way radio communication devices. However, eliminating, or substantially eliminating the conventional external antenna in two-way radio communication devices would be attractive to users of such devices for a number of reasons, including that it would make such devices easier to carry.

Accordingly, there is a need for an antenna structure that can be used in portable two-way radio devices that substantially eliminates or minimizes the need for an external antenna.

BRIEF DESCRIPTION OF THE FIGURES

The accompanying figures, where like reference numerals refer to identical or functionally similar elements throughout the separate views, together with the detailed description below, are incorporated in and form part of the specification, and serve to further illustrate embodiments of concepts that

2

include the claimed invention, and explain various principles and advantages of those embodiments.

FIG. 1 is a block diagram of a portable radio communication device using a hybrid antenna structure in accordance with some embodiments;

FIG. 2 is an exploded view of a portable radio communication device using a hybrid antenna in accordance with some embodiments;

FIG. 3 is a schematic diagram of a switch circuit for selecting a tap point in a hybrid antenna in accordance with some embodiments;

FIG. 4 is a wrapped conductor element having a meander element with multiple selectable tap points in accordance with some embodiments;

FIG. 5 is a wrapped antenna element having a meander element and a spiral element with multiple selectable tap points in accordance with some embodiments;

FIG. 6 is a wrapped antenna element having a meander element and a helical element with multiple selectable tap points in accordance with some embodiments;

FIG. 7 is a return loss plot versus frequency showing the effect of selecting different tap points in a hybrid antenna in accordance with some embodiments; and

FIG. 8 is a flow chart diagram of a method of operating a hybrid antenna in accordance with some embodiments.

Skilled artisans will appreciate that elements in the figures are illustrated for simplicity and clarity and have not necessarily been drawn to scale. For example, the dimensions of some of the elements in the figures may be exaggerated relative to other elements to help to improve understanding of embodiments of the present invention.

The apparatus and method components have been represented where appropriate by conventional symbols in the drawings, showing only those specific details that are pertinent to understanding the embodiments of the present invention so as not to obscure the disclosure with details that will be readily apparent to those of ordinary skill in the art having the benefit of the description herein.

DETAILED DESCRIPTION

Embodiments include a hybrid internal antenna structure suitable for use with a portable radio communication device. The hybrid antenna structure can include a feed line connected to a radio frequency (RF) circuit. A switching circuit can be included that has an input connected to the feed line and which has a plurality of selectable outputs. The switching circuit can be operable to connect the input to a selected one of the plurality of selectable outputs. The internal antenna structure can further include an inductive matching tail element connected between the feed line and a reference potential, and a wrapped conductor element having a plurality of tap points along a length of the wrapped conductor element. Each of the plurality of selectable outputs is coupled exclusively to a respective one of the plurality of tap points.

FIG. 1 is a block diagram of a portable radio communication device **100** using a hybrid antenna structure **102** in accordance with some embodiments. The portable radio communication device **100** can be any type of radio communication device, including a device that only transmits radio signals, a device that only receives radio signals, or a device that both transmits and receives radio signals. In some embodiments the portable radio communication device **100** can be a portable two-way radio communication device such as those commonly used by public safety organizations (e.g. police, fire/rescue) and other organizations that desire near instant communication.

The hybrid antenna structure **102** is coupled to a radio frequency (RF) circuit **104**, which can include an RF receiver, an RF transmitter, or both (transceiver). In some embodiments the RF circuit can operate in the Very High Frequency (VHF) band, which includes frequencies from 30 MHz to 300 MHz. The RF circuit **104** is coupled in particular to a feed line **106**, which if further coupled to a switching circuit **108** and an inductive matching tail element **126**. The feed line **106** is further coupled to a switching circuit **108** which is used to select a path **110**, **112** or **114** through which to connect the feed line **106** to a wrapped conductor element **116**. The wrapped conductor element **116** is a conductor having a path that alternates direction along the path (i.e. wrapping) to achieve a length directly from terminus to terminus that is shorter than its electrical length (i.e. along the path). Examples of wrapped conductor elements include, for example, a helical element **118**, a meander element **120**, and a spiral element **122**. A helical element **118** is a conductor that winds around a space somewhat like the threads of a screw. A meander element **120** can be formed in a plane and portions of the meander element alternate direction in a "back and forth" pattern. A spiral element **122** can also be formed in a plane and generally winds around a central region, increasing or decreasing in diameter relative to the central region, depending on the direction traversed along the path of the spiral element **122**. These elements **118**, **120**, **122** can be combined serially as well. Furthermore, a meander element **120** and a spiral element **122** can be formed in a flexible circuit board that can be curved or bent to fit into an interior space of the housing of a portable radio communication device **100**, while the helical element **118** can be wound around a supporting member in the interior space of a portable radio communication device **100**. The wrapped conductor element **116** can be further connected to an additional antenna element, such as an external antenna element **124**.

The switching circuit **108** has an input connected to the feed line **106**, and it has several outputs (i.e. **110**, **112**, **114**) that each connect to a different tap point along the length of the wrapped conductor element **116** to achieve a different frequency response. Thus, as shown, the portable radio communication device **100** can be operable over three different bands with each band corresponding to a different tap point on the wrapped conductor element **116**. When a user selects an operating frequency for the portable radio communication device **100**, a controller **136** of the RF circuit **104** can configure the switching circuit **108** to connect the feed line **106** to the appropriate output **110**, **112**, **114** which are each connected to a different tap point along the length of the wrapped conductor element **116**.

Likewise, the inductive matching tail element **126** can be tuned to match the selected frequency using a tuning circuit **130**. The inductive matching tail element **126** includes a meander element **128** which is connected between the feed line **106** and a reference potential such as a ground potential. The tuning circuit **130** changes a matching impedance of the inductive matching element **126** based on the selected operating frequency of the RF circuit **104**, and can be controlled by the controller **136** or the RF circuit **104**. The tuning circuit **130** can be configured to connect different points along the meander element **128** to the reference potential to adjust its inductance value. The inductive matching tail element is used to match the capacitance presented to the feed line **106** by the hybrid antenna structure **102** as is common in electrically small antenna structures.

The controller **136** can be a microprocessor or microcontroller that is coupled to a memory **138** in which instruction code is stored or instantiated for execution by the controller

138. To facilitate voice and audio communication in some embodiments an audio processor **140** can be used to convert received acoustic signals (e.g. speech) that produce an analog signal at a microphone **142** into a format for transmission, which can include digitizing the analog signal produced by the microphone **142**. Signals produced by the microphone in response to acoustic signals can be provided to the RF circuit **104** for transmission. Likewise, audio information received by the portable radio communication device that is encoded in a radio signal can be extracted from the radio signals by the RF circuit **104** and provided to the audio processor **140** to be played over a speaker **144**. The controller **136** interfaces with a user interface **146** that can include elements such as a graphical display **148** for displaying information visually, a keypad **150**, and other buttons/knobs to allow a user to enter information and make selections. When a user operates the portable radio device **100**, the user can select an operating band (i.e. an RF band) or a channel that is in a particular band. Upon selecting a band or a channel, the portable radio device **100** configures switching circuit **108** and tuning circuit **130** accordingly to modify the electrical properties of the hybrid antenna structure **102** in accordance with the selected frequency band or channel. In some embodiments the external antenna element **124** can be used and can include a helical, whip, or other antenna element. Generally the external antenna element **124** is small enough to be considered a "stub," protruding from the portable radio device **100** only a small length, on the order of less than two inches, which is much shorter than a conventional VHF external antenna (i.e. where the entire antenna is located external to the portable radio device).

FIG. 2 is an exploded view of a portable radio communication device **200** using a hybrid antenna in accordance with some embodiments. Those skilled in the art will appreciate that the exemplary view shown here is not intended to imply any particular manufacturing or assembly process and that a device **200** can be assembled in numerous ways without departing from the spirit and scope of the various embodiments. The portable radio communication device **200** includes a housing **202** in which the hybrid antenna structure and other circuitry and components are assembled. The housing **202** can be fabricated of polymeric material and forms an interior space **232** into which components are placed. Some circuitry for the portable radio communication device **200** can be placed on a circuit board **206** that can include an RF circuit **208** and a switching circuit **210**, which can be comparable to RF circuit **104** and switching circuit **108**, respectively, of FIG. 1. Accordingly, there will be a feed line between the RF circuit **208** and the switching circuit **210** to which an inductive matching tail element **212** is coupled, as indicated by arrow **226**.

The switching circuit **210** contains switches that can be configured to connect the feed line to various locations on a wrapped conductor element **214**, such as through a flexible circuit board connector **216**. The flexible circuit board connector **216** can have several pads for connecting to corresponding outputs of the switching circuit **210**, and conductors **218** that connect the pads to various locations or tap points on the wrapped conductor element **214**. The wrapped conductor element **214** contains, for example, a meander element, a helical element, a spiral element, or combinations of those elements. In some embodiments the wrapped conductor element **214** can be formed in a flexible circuit board that is bent or turned from a flat configuration to conform to the interior periphery of the housing **202**. In some embodiments the wrapped conductor element **214** itself can be wrapped around the circuit board **206** and other components assembled into

5

the housing **202** of the portable radio communication device **200** to at least partially encircle the circuit board and/or other components. As such the wrapped conductor can be disposed around the inner periphery of the housing **202** (i.e. the inside surface). The wrapped conductor element **214** can have a termination point **215** that can be connected to an external antenna element **220** upon assembly of the portable radio communication device **200**. The external antenna can be mounted in a port of electrical connector **230**, as indicated by arrow **228**, to connect to the termination point **215** of the wrapped conductor element **214**. Thus, once assembled, the hybrid antenna structure, including the switching circuit **210**, inductive matching tail element **212**, and wrapped conductor element **214**, are disposed in the interior **232** of the housing **202**. The external antenna element **220** can be used to augment the effectiveness of the internal antenna structure for certain frequency bands.

FIG. 3 is a schematic diagram of a switch circuit **302** for selecting a tap point in a hybrid antenna **300**, in accordance with some embodiments. The switch circuit **302** includes a plurality of switches or switch circuits **304**, **306**, **308**. Each switch circuit **304**, **306**, **308** is connected to a common input **310**, which can be a feed line such as feed line **106** of FIG. 1, and each switch circuit **304**, **306**, **308** has a unique output **318**, **320**, **322**, respectively. Each switch circuit **304**, **306**, **308** is controlled by a respective enable line **312**, **314**, **316**, which can be controlled by the RF circuit or a controller of the portable radio communication device. The input line **310** is also coupled to an inductive matching tail element **311**, which is represented here as a lumped component but in actuality can be formed by a tunable meander element. Each output **318**, **320**, **322** is connected to the wrapped conductor element **324** at a different location along a length of the wrapped conductor element **324**. The wrapped conductor **324** shown here is broken into three portions **326**, **328**, **330**, which represent different portions along the length of the wrapped conductor element **324**, and which are electrically connected contiguously along a path length of wrapped conductor **324**. Accordingly, output **318** can be connected to a tap point on portion **326**, which can be an initial or starting portion of the wrapped conductor element **324**. Output **320** can be connected to a tap point on portion **328**, which can be a first intermediate portion after the initial portion along the length of wrapped conductor **324**. Output **322** can be connected to a tap point on portion **330**, which can be a second intermediate portion after the initial and first intermediate portions along the length of wrapped conductor element **324**.

By connecting the input **310** to different tap points along the wrapped conductor **324**, the resulting frequency response of the hybrid antenna structure **300** can be changed selectively. So each of switch circuit **304**, **306**, and **308** can be selectively switched on in accordance with a selected operating frequency band. The switch circuits **304**, **306**, **308** can be implemented by PIN diodes, micro-electromechanical switches (MEMS), transistors, and so on, as will be apparent to those of skill in the art.

FIG. 4 is a wrapped conductor element **400** having a meander element with multiple selectable tap points in accordance with some embodiments. The wrapped conductor element **400** can be fabricated on a substrate **402**, which can be a circuit board or a flexible circuit board. A conductor **404** is disposed on the substrate **402** in a meander shape between a first terminus **406** and a second terminus **418**. In general the conductor **404** follows a path that alternates right to left, then left to right (as viewed on the page), advancing in a direction generally perpendicular (up the page in this example) to the direction of each right/left meander segment. Thus, the dis-

6

tance directly from the first terminus **406** to the second terminus **418** (i.e. a straight line between them) is substantially shorter than the length along the path of the meander. A first pad **412** can be connected to first output of a switch circuit (not shown) and further connected to a first tap point at the first terminus **406**. A second pad **414** can be connected to a second output of the switch circuit and further connected to a tap point at a first intermediate point **408** along the meander element. A third pad **416** can be connected to a third output of the switch circuit and further connected to a tap point at a second intermediate point **410** along the meander element. The frequency response at different locations along the meander element differs, thus a point corresponding to a desired frequency band is selected for each tap point. More or less than three tap points can be chosen, along with a respective number of outputs of the corresponding switch circuit, if more or less than three frequency bands are to be used by the portable radio communication device. In some embodiments the wrapped conductor element **400** can be implemented on a flexible circuit board which can be bent, curved, or folded along lines **420**, **422**, **424**, for example, as indicated by arrows **426**, **428**, to form the flexible circuit board around the interior periphery of the portable radio communication device. An external antenna element can be connected to the second terminus **418**.

FIG. 5 is a wrapped antenna element **500** having a meander element **502** and a spiral element with multiple selectable tap points in accordance with some embodiments. The meander element **502** comprises portion of a conductor trace disposed on a substrate (or simply a metal piece that supports itself) in a meander shape. The meander portion is shown electrically connected in series with a spiral element that spirals around a central region with spiral segments **506**. As shown, the meander portion **502** in the interior of the spiral portion in accordance with some embodiments, and the spiral portion spirals around the meander portion to a terminus **508** which can be connected to an external antenna element. Three pads **510**, **512**, **514** can be used to connect corresponding outputs of a switch circuit to a first tap point **516**, a second tap point **518**, or a third tap point **520**, respectively, where each tap point **516**, **518**, **520** correspond to different frequency responses for different operating frequencies or frequency bands. As in FIG. 4 the wrapped conductor element **500** can be formed on a flexible circuit board and bent or curved around line **522**, **524**, in the direction of arrows **526**, **528**, respectively, to form the wrapped conductor element **500** around the inside of a portable radio communication device.

FIG. 6 is a wrapped antenna element **600** having a meander element **604** and a helical element **602** with multiple selectable tap points in accordance with some embodiments. A circuit element **606** can be used to connect pads **608**, **612**, and **616** to tap points **610**, **614**, **618**, respectively. Pads **608**, **612**, and **626** can be further connected to corresponding outputs of a switching circuit. Each tap point **610**, **614**, or **618** can be selected through the switching circuit for a desired operating frequency. Unlike meander and spiral elements, the helical element **602** is wound around a space, such around a supporting member which can be hollow so as to allow the assembly of circuitry and other components inside the center portion of the helical element **602**. A terminus **620** can be connected to an external antenna element (or any other antenna element, including another wrapped conductor section).

In FIGS. 4-6 various exemplary embodiments of wrapped conductor elements are shown. These are not meant to represent the entirety of possible forms, designs, and shapes of wrapped conductor elements, and numerous other forms of wrapped conductor elements and combinations of wrapped

7

conductor elements can occur to those skilled in the art. A wrapped conductor element is used to provide and electrically long path in a physically short space, the terms “long” and “short” being relative here. Furthermore, to achieve the desired frequency response, the wrapped conductor element is tapped at different points for connection, though a switching circuit, to a feed line (which can operate for transmitting, receiving, or both). Since the conductor (i.e. the metal) in a wrapped conductor element has portions of the conductor near other portions of the conductor, a wrapped conductor element presents more capacitance at the feed line point than, for example, a straight whip monopole antenna element. Accordingly, to match the load of the hybrid antenna at the feed line, an inductive matching tail element is used that is connected between the feed line and a reference potential. Since the frequency response of the wrapped conductor element is selected in correspondence with a selected frequency or frequency band, the inductive matching tail element can be tuned accordingly (i.e. by bypassing sections of the meander used to implement the inductive matching tail element) to maintain a proper impedance match at the feed line.

FIG. 7 is a graph 700 of return loss versus frequency, showing the effect of selecting different tap points in a hybrid antenna, in accordance with some embodiments. Return loss is graphed along the vertical axis 702 while frequency is graphed along the horizontal axis 704. The 0 decibel (dB) line 706 is approximately two thirds of the way up the vertical axis 702. There are three different plots on the graph represented by a solid line, a dotted line, and a dashed line. Each plot represents selection of a different tap point in a wrapped conductor such as those discussed in reference to FIGS. 1-6. For example, the solid line represents the frequency response from the feed line for selection of a first tap point, the dotted line represents the frequency response from the feed line for selection of a second tap point, and the dashed line represents the frequency response from the feed line for selection of a third tap point. Selection of the first tap point corresponds to a first frequency band 706, selection of the second tap point corresponds to a second frequency band 708, and selection of the third tap point correspond to a third frequency band 710. Thus, for example, if the user of the portable radio communication device selects an operating frequency in the second frequency band 708, the switching circuit will be configured to connect the feed line to the second tap point. A frequency selection in the first band will result in the switching circuit being configured to connect the feed line to the first tap point, and so on.

FIG. 8 is a flow chart diagram of a method 800 of operating a hybrid antenna in a portable radio communication device, in accordance with some embodiments. At the start 802, the portable radio communication device is powered on and ready for operation. Commencing in step 804, the user can select or indicate a desired frequency of operation. The frequency selection can be performed by, for example, manipulating a frequency dial or knob, entering a channel number in a graphical user interface, selecting an organization from a list of organizations in a graphical user interface, and so on. Upon receiving the indication of the selected frequency from the user, the portable radio communication device determines the corresponding tap point in step 806. For example, the first, second, and third bands 706, 708, and 710, respectively, in FIG. 7 can be represented in a memory of the portable radio communication device by the boundary frequencies of each band. When a user indicates a frequency, directly or indirectly, the portable communication device can map that frequency into one of the bands, and select the corresponding tap point. Once the corresponding tap point is determined, the

8

portable radio communication device then configures the switching circuit in step 808 to connect the RF circuit, via a feed line, to the corresponding tap point of the wrapped conductor element. In order to preserve the proper impedance match, in step 810 the inductive matching tail element is likewise tuned by adjusting the inductance coupled to the feed line. The method ends at step 812 and the portable radio communication device can then commence radio communication. The method 800 can be repeated when the user desires to operate on a different frequency.

The embodiments provide the benefit of a compact antenna structure that can be used entirely, or almost entirely, within a portable radio communication device operating in VHF frequency bands, which allows manufacturers to design portable radio communications devices for operating in the VHF range using design styles that are familiar, and preferable to present day users. Conventional antenna designs, such as an external wideband whip type monopole, can be avoided by use of a wrapped conductor that is tapped at various points along the electrical length of the wrapped conductor element. Various wrapped conductor element designs are available that can be used in accordance with the embodiments. Tap points along the length of the wrapped conductor element can be determined empirically, based on desired frequency response for various operating frequency bands.

In the foregoing specification, specific embodiments have been described. However, one of ordinary skill in the art appreciates that various modifications and changes can be made without departing from the scope of the invention as set forth in the claims below. Accordingly, the specification and figures are to be regarded in an illustrative rather than a restrictive sense, and all such modifications are intended to be included within the scope of present teachings.

The benefits, advantages, solutions to problems, and any element(s) that may cause any benefit, advantage, or solution to occur or become more pronounced are not to be construed as a critical, required, or essential features or elements of any or all the claims. The invention is defined solely by the appended claims including any amendments made during the pendency of this application and all equivalents of those claims as issued.

Moreover in this document, relational terms such as first and second, top and bottom, and the like may be used solely to distinguish one entity or action from another entity or action without necessarily requiring or implying any actual such relationship or order between such entities or actions. The terms “comprises,” “comprising,” “has,” “having,” “includes,” “including,” “contains,” “containing” or any other variation thereof, are intended to cover a non-exclusive inclusion, such that a process, method, article, or apparatus that comprises, has, includes, contains a list of elements does not include only those elements but may include other elements not expressly listed or inherent to such process, method, article, or apparatus. An element preceded by “comprises . . . a”, “has . . . a”, “includes . . . a”, “contains . . . a” does not, without more constraints, preclude the existence of additional identical elements in the process, method, article, or apparatus that comprises, has, includes, contains the element. The terms “a” and “an” are defined as one or more unless explicitly stated otherwise herein. The terms “substantially”, “essentially”, “approximately”, “about” or any other version thereof, are defined as being close to as understood by one of ordinary skill in the art, and in one non-limiting embodiment the term is defined to be within 10%, in another embodiment within 5%, in another embodiment within 1% and in another embodiment within 0.5%. The term “coupled” as used herein is defined as con-

nected, although not necessarily directly and not necessarily mechanically. A device or structure that is “configured” in a certain way is configured in at least that way, but may also be configured in ways that are not listed.

It will be appreciated that some embodiments may be comprised of one or more generic or specialized processors (or “processing devices”) such as microprocessors, digital signal processors, customized processors and field programmable gate arrays (FPGAs) and unique stored program instructions (including both software and firmware) that control the one or more processors to implement, in conjunction with certain non-processor circuits, some, most, or all of the functions of the method and/or apparatus described herein. Alternatively, some or all functions could be implemented by a state machine that has no stored program instructions, or in one or more application specific integrated circuits (ASICs), in which each function or some combinations of certain of the functions are implemented as custom logic. Of course, a combination of the two approaches could be used.

Moreover, an embodiment can be implemented as a computer-readable storage medium having computer readable code stored thereon for programming a computer (e.g., comprising a processor) to perform a method as described and claimed herein. Examples of such computer-readable storage mediums include, but are not limited to, a hard disk, a CD-ROM, an optical storage device, a magnetic storage device, a ROM (Read Only Memory), a PROM (Programmable Read Only Memory), an EPROM (Erasable Programmable Read Only Memory), an EEPROM (Electrically Erasable Programmable Read Only Memory) and a Flash memory. Further, it is expected that one of ordinary skill, notwithstanding possibly significant effort and many design choices motivated by, for example, available time, current technology, and economic considerations, when guided by the concepts and principles disclosed herein will be readily capable of generating such software instructions and programs and ICs with minimal experimentation.

The Abstract of the Disclosure is provided to allow the reader to quickly ascertain the nature of the technical disclosure. It is submitted with the understanding that it will not be used to interpret or limit the scope or meaning of the claims. In addition, in the foregoing Detailed Description, it can be seen that various features are grouped together in various embodiments for the purpose of streamlining the disclosure. This method of disclosure is not to be interpreted as reflecting an intention that the claimed embodiments require more features than are expressly recited in each claim. Rather, as the following claims reflect, inventive subject matter lies in less than all features of a single disclosed embodiment. Thus the following claims are hereby incorporated into the Detailed Description, with each claim standing on its own as a separately claimed subject matter.

We claim:

1. An internal antenna structure for a portable radio communication device, comprising:
a feed line connected to a radio frequency (RF) circuit;
a switching circuit having an input connected to the feed line and having a plurality of selectable outputs, the switching circuit is operable to connect the input to a selected one of the plurality of selectable outputs;
an inductive matching tail element connected between the feed line and a reference potential; and
a wrapped conductor element having a plurality of tap points along a length of the wrapped conductor element; wherein each of the plurality of selectable outputs of the switching circuit is coupled exclusively to a respective one of the plurality of tap points.

2. The internal antenna structure of claim 1, wherein the inductive matching tail element is a conductor having a meander shape.

3. The internal antenna structure of claim 1, wherein the wrapped conductor element comprises a meander element.

4. The internal antenna structure of claim 1, wherein the wrapped conductor element comprises a helical element coupled to the meander element.

5. The internal antenna structure of claim 1, wherein the wrapped conductor element comprises a meander element coupled to a spiral element.

6. The internal antenna structure of claim 1, wherein the wrapped conductor element is formed in a flexible circuit board that is wrapped around an internal space of the portable radio communication device.

7. The internal antenna structure of claim 1, wherein the switching circuit connects the input to the selected one of the plurality of selectable outputs based on a selected operating frequency of the RF circuit.

8. The internal antenna structure of claim 7, wherein the selected operating frequency is a frequency band from 30 MHz to 300 MHz.

9. The internal antenna structure of claim 1, wherein the wrapped conductor element has a termination connected to an external antenna element.

10. The internal antenna structure of claim 1, wherein the inductive matching tail element is connected to the reference potential through a tuning circuit that changes a matching impedance of the inductive matching element based on an operating frequency of the RF circuit.

11. A method of operating a portable radio communication device, comprising:

receiving an indication of a selected operating frequency;
determining a switching configuration for a switching circuit having an input connected to a radio frequency (RF) circuit via a feed line and a plurality of outputs, each one of the plurality of outputs connected to a respective tap point along a length of a wrapped conductor, wherein each tap point corresponds to a frequency band;
configuring the switching circuit to connect the feed line to a tap point corresponding to the selected operating frequency range; and
adjusting an inductive matching tail element connected between the feed line and a reference potential based on the selected operating frequency.

12. The method of claim 11, wherein receiving the indication of the selected operating frequency comprises receiving a channel section via a user interface of the portable radio communication device.

13. The method of claim 11, wherein configuring the switching circuit comprises configuring the switching circuit to connect the feed line to a tap point on a meander element of the wrapped conductor element.

14. A portable radio communication device, comprising:
a housing;
a circuit board disposed in the housing;
a wrapped conductor element disposed around an inner periphery of the housing so as to at least partially encircle a portion of the circuit board;
a radio frequency (RF) circuit connected to a feed line;
a switching circuit that selectively connects the feed line to one of a plurality of tap points along a length of the wrapped conductor element, wherein each tap point corresponds to a different frequency band; and
an inductive matching tail element connected between the feed line and a reference potential, and wherein the

11

inductive matching tail element is selectively tuned in correspondence with a selection of one of the plurality of tap points.

15. The portable radio communication device of claim 14, wherein the inductive matching tail element is a conductor having a meander shape. 5

16. The portable radio communication device of claim 14, wherein the wrapped conductor element comprises a meander element formed on a flexible circuit board member.

17. The portable radio communication device of claim 14, wherein the wrapped conductor element comprises a helical element coupled to the meander element, wherein the helical element and the meander element are formed on a substrate that fits around the inner periphery of the housing. 10

18. The portable radio communication device of claim 14, wherein the wrapped conductor element comprises a meander element coupled to a spiral element, wherein the spiral element and the meander element are formed on a flexible circuit board member. 15

19. The portable radio communication device of claim 14, wherein the switching circuit connects the input to the selected one of the plurality of selectable outputs based on a selected operating frequency of the RF circuit. 20

20. The portable radio communication device of claim 14, wherein the wrapped conductor element has a termination connected to an external antenna element. 25
